1 Introduction

The password manager project represents a significant endeavor aimed at addressing the pressing need for secure password management in today's digital landscape. With the escalating reliance on online platforms and services, the imperative for robust information security practices has become paramount. The primary goal of the password manager is to furnish users with a dependable and secure solution for managing their passwords offline. In recent times, the surge in cyber threats such as data breaches and identity theft has underscored the vulnerability of personal information stored online. Conventional methods of password management, including the use of easily guessable passwords or jotting them down on paper, are no longer viable options for ensuring the security of sensitive data. The project's significance transcends individual users and encompasses broader implications for information security. By advocating best practices in password management, such as the adoption of complex and unique passwords for each account, the project contributes to bolstering the overall resilience of digital ecosystems against cyber threats.

2 Objectives

The primary objective of the password manager is to provide users with a reliable solution for managing their passwords securely offline. By storing sensitive data locally on their devices, the app mitigates the risks associated with online storage and augments user control over their personal information. Through its robust security features and emphasis on best practices in password management, the project endeavors to empower users to safeguard their online identities and fortify their data against unauthorized access.

3 Project Features

3.1 Login Authentication:

The vault mobile application features a robust login authentication system to verify users' identities before granting access to their password vault. This authentication mechanism ensures that only authorized users can view and manage their passwords securely.

3.2 Password Hashing

Robust authentication mechanisms, including password hashing and salting, were implemented to verify user identities and prevent unauthorized access to the password vault.

3.3 Two-Factor Authentication (2FA)

The mobile app incorporates two-factor authentication (2FA) as an additional layer of security. Users are required to provide a secondary form of authentication, such as a one-time code sent to their registered email or mobile device, to verify their identity before gaining access to their account.

3.4 Biometric Authentication

Biometric authentication methods, such as fingerprint or facial recognition, were integrated into the mobile app to enhance user convenience and strengthen authentication security. Users can securely access their password vault using their unique biometric data.

3.5 Password Generation:

Integrated within the mobile application is a password generation tool that empowers users to create complex and secure passwords. Users have the flexibility to specify parameters such as length, character types, and complexity to generate passwords tailored to their individual needs.

3.6 Secure Storage:

Passwords stored within the vault mobile application are encrypted both during transmission and while at rest within the device. Strong encryption algorithms and secure storage practices are employed to safeguard user data from unauthorized access, providing peace of mind to users regarding the security of their passwords.

3.7 Download Backup File:

The mobile application provides users with the option to download a backup file containing all their saved passwords. This backup file is encrypted and accessible only to the user, offering an additional layer of security and convenience for data retrieval and backup purposes.

4 Problem identification

4.1 Data Breaches:

Traditional online password managers often store user passwords on remote servers, making them susceptible to data breaches. The vault mobile application mitigates this risk by storing passwords locally within the user's mobile device, reducing the likelihood of unauthorized access to sensitive data.

4.2 Password Weaknesses:

Users commonly employ weak or easily guessable passwords, putting their accounts at risk of compromise. The password generation feature of the vault application encourages the creation of strong, complex passwords, thereby bolstering the overall security posture of user accounts.

4.3 Unauthorized Access:

Weak authentication mechanisms can lead to unauthorized access to user accounts. The vault application addresses this challenge by implementing a robust login authentication system within the mobile app. Ensuring that only authorized users can access their password vault.

4.4 Data Interception:

During transmission, passwords transmitted over unsecured networks are vulnerable to interception by malicious actors. The vault mobile application employs encryption protocols to secure data transmission, safeguarding passwords from interception and ensuring data confidentiality.

4.5 Single Point of Failure:

Centralized password management systems present a single point of failure, where a breach or compromise can compromise all stored passwords. The vault application decentralizes password storage by storing passwords locally on users' mobile devices, reducing the impact of a potential breach.

4.6 Offline Security:

Many password management systems require an internet connection for access, posing security risks when users need to access their passwords offline. The vault mobile application addresses this challenge by offering offline functionality, enabling users to access and manage passwords even without an internet connection, thereby minimizing security risks associated with online access.
